Trending Matters:

Help prevent breeding mosquitoes that carry West Nile & Zika

- ✓ Don't let standing water collect on your property!
- ✓ Check for turned up garbage can lids, grill covers, and children's toys.
- ✓ Empty, clean & refill birdbaths & wading pools frequently.

Warm weather means West Nile season

Predicting West Nile virus activity is a lot like predicting the weather, as it can change week to week. The key factors in determining high or low levels of West Nile virus activity are temperature and rainfall.

Although people usually notice mosquitoes during rainy conditions, those mosquitoes are commonly called floodwater or nuisance mosquitoes and typically do not carry West Nile virus.

In hot, dry weather, mosquitoes that do carry West Nile virus breed in stagnant water, like street catch basins and ditches, and multiply rapidly. Remember, it's always a good idea to regularly inspect your home and yard for sources of standing water where these mosquitoes are likely to breed.

This year the Health Department is also actively monitoring for the Zika virus. We need to keep in mind that in Kane County, the public at large is currently at extremely low risk of local transmission of the Zika Virus.

The primary type of mosquito that has been found to transmit Zika virus (*Aedes aegypti*) is rarely found in Illinois. However, we will continue to provide up to date information as we receive it.

Check our website for more Zika information:
http://www.kanehealth.com/wnv_surveillance.htm
Those persons planning to travel to areas where the Zika virus is found should take the standard precautions for preventing mosquito bites. Also, it has been shown that the virus can be spread during sex by a man infected with Zika to his partner.

The Culex mosquito (right) carrier of the West Nile Virus
Commonly found in the Midwestern USA

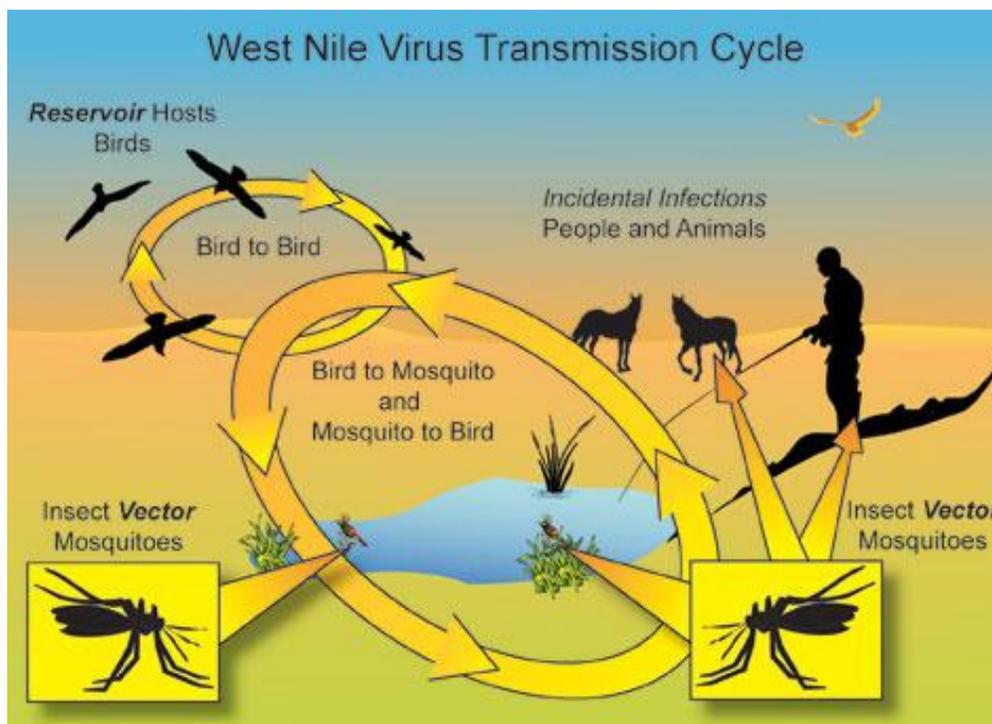

The Aedes mosquito (right) carrier of the Zika Virus
Currently **NOT** commonly found in the Midwestern USA

Annual monitoring for West Nile Virus

The Health Department conducts several activities to monitor West Nile virus. KCHD staff maintains mosquito traps throughout the county as a way to monitor this activity. The mosquitoes are trapped and then taken back to the Health Department where a test can tell whether West Nile virus is present. You can view trap locations, find up-to-date West Nile monitoring data, historical information and more when you visit the West Nile page: http://www.kanehealth.com/west_nile.htm.

Sizzling summer weather brings its own kind of dangers

It's midway through June and we've already had a taste of hot, humid weather.

Is this what we can expect for the rest of the summer of 2016?

No one knows for sure right now, but what we do know is that we can prepare ourselves for the type of heat that we know can come our way. According to the National Weather Service (NWS), heat is one of the leading weather-related killers in the United States, resulting in hundreds of fatalities each year.

Historically, heat waves have had a devastating effect on people. In 1995 more than 700 deaths in the Chicago area were attributed to heat, making it the deadliest weather event in Chicago history. We also know that in August 2003, a record heat wave in Europe claimed an estimated 50,000 lives. And in 2015, as many as 2,500 people died during a heat wave in India. We are seeing blistering temperatures this month in the American Southwest.

The [Kane County Office of Emergency Management](#) and Kane County Health Department monitor potential extreme heat conditions in the County and will take action based on extreme heat alerts issued by NWS.

Heat alerts, described to the right, will be posted on our [Web site home page](#) under the NEWS heading in the right hand column.

In addition, **air quality alerts** are often issued during high heat days.

For up-to-date advisories on air pollution action days, please check our [Web site home page](#) where alert days are also posted under the NEWS heading in the right hand column.

Four terms to remember:

Excessive Heat Outlook:

Using a combination of temperature and humidity over a certain number of days the Excessive Heat Outlook is designed to provide an indication of areas where people and animals may need to take precautions against the heat during the months of May to November.

Excessive Heat Watch:

Issued when conditions are favorable for an excessive heat event in the next 12 to 48 hours. A Watch is used when the risk of a heat wave has increased but its occurrence and timing is still uncertain. A Watch provides enough lead time so that those who need to prepare can do so.

Heat Advisory:

Issued within 12 hours of the onset of a heat index of at least 105 degrees F, but less than 115 degrees F, for less than three hours per day, or nighttime lows above 80 degrees for two consecutive days.

Excessive Heat Warning:

Issued within 12 hours of the onset of a heat index of at least 105 degrees for more than three hours per day for two consecutive days, or heat index more than 115 degrees F for any period of time. Learn more here:

Our air quality alert looks like this:
